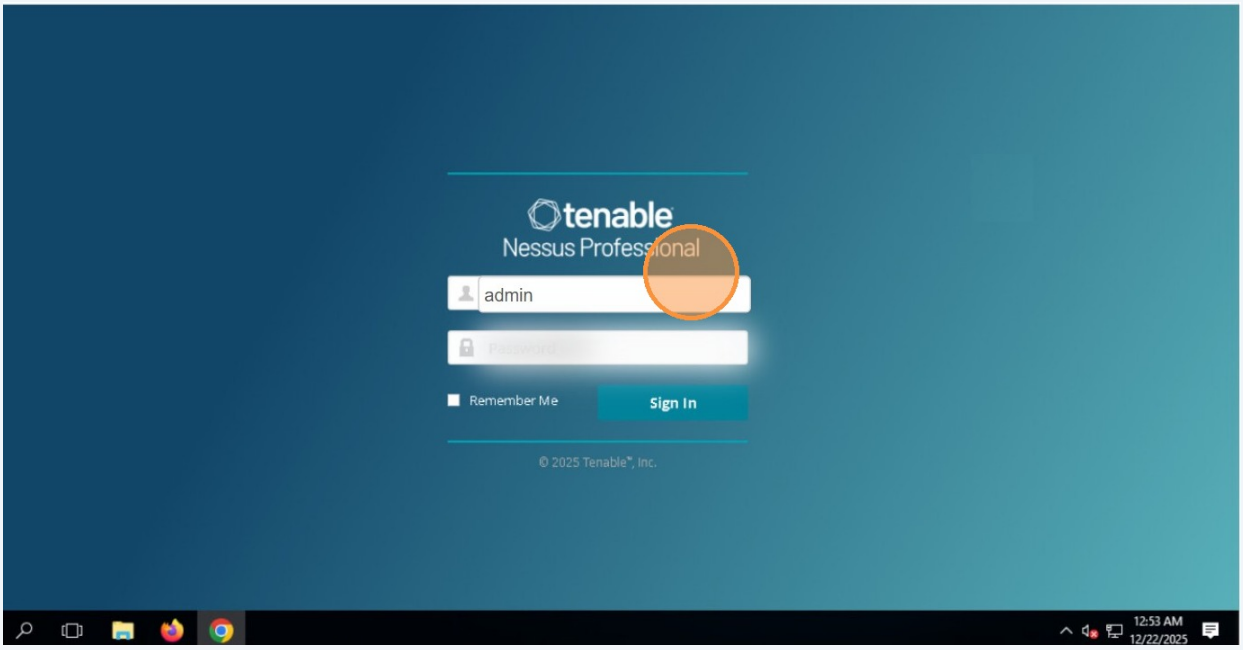
Nessus Network Scan

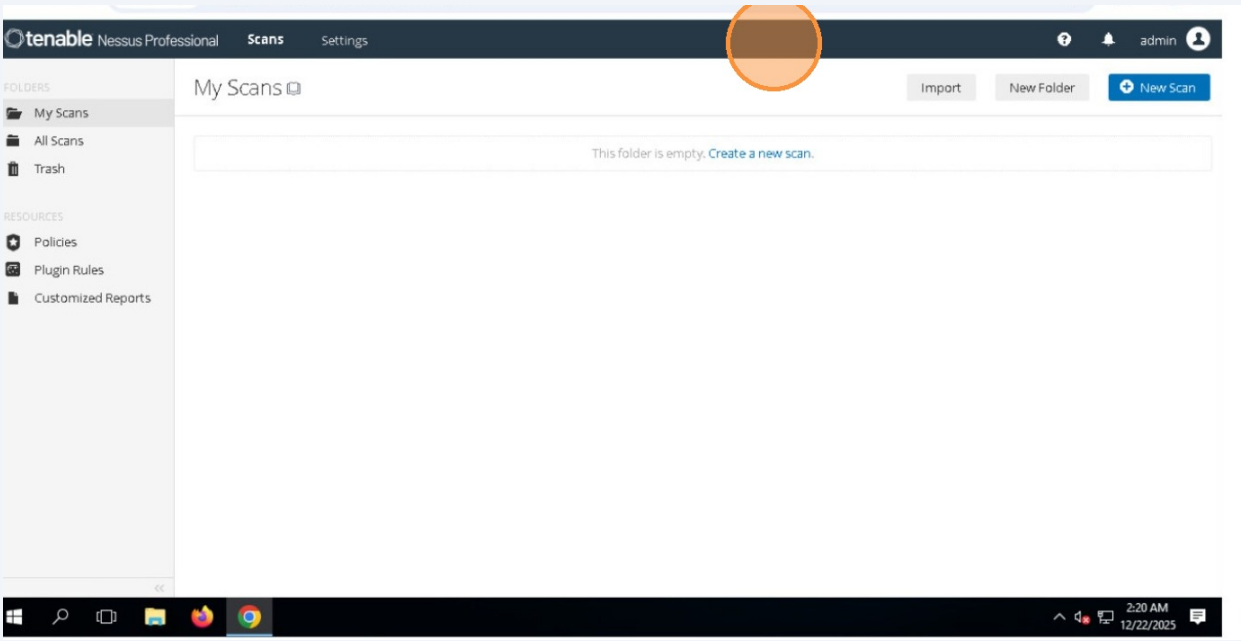
Conducted a network vulnerability assessment using Nessus to identify open ports, services, and potential security risks within a target system. This project demonstrates practical experience in vulnerability scanning, service enumeration, and interpreting scan results to assess network security posture.

Cybersecurity-Portfolio: https://github.com/ingridsec/Projects

1 I initiated the assessment by accessing the Nessus vulnerability scanner, a widely used tool for identifying security weaknesses across networked systems. This platform enables automated scanning of ports, services, and known vulnerabilities.



2 I configured a new scan by selecting an appropriate scan template. Choosing the correct scan type ensures that the assessment targets relevant vulnerabilities and aligns with the intended scope of the analysis.



3 I defined the target system by specifying its IP address. Clearly identifying the target ensures that the scan remains controlled and focused on authorized assets.

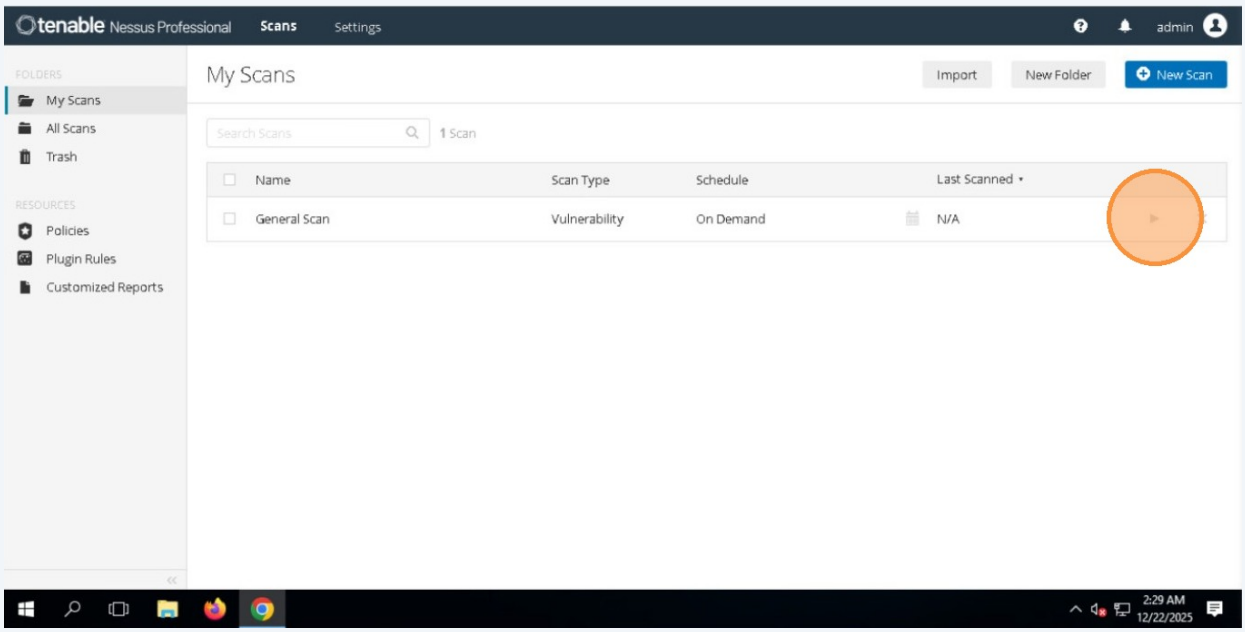
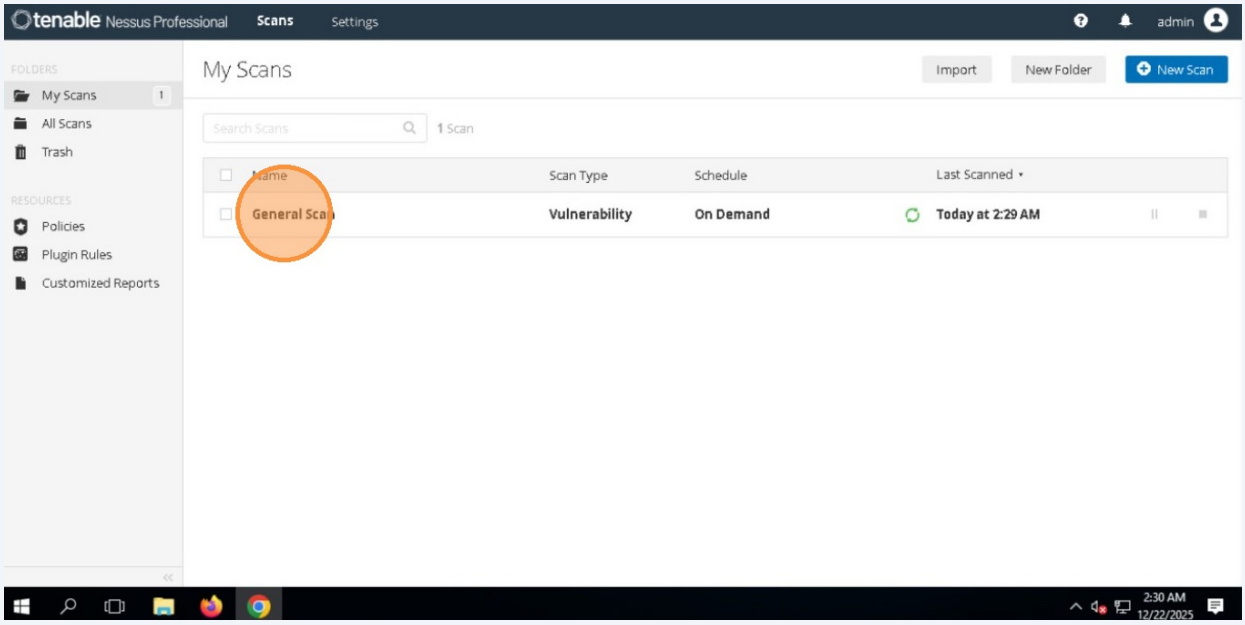
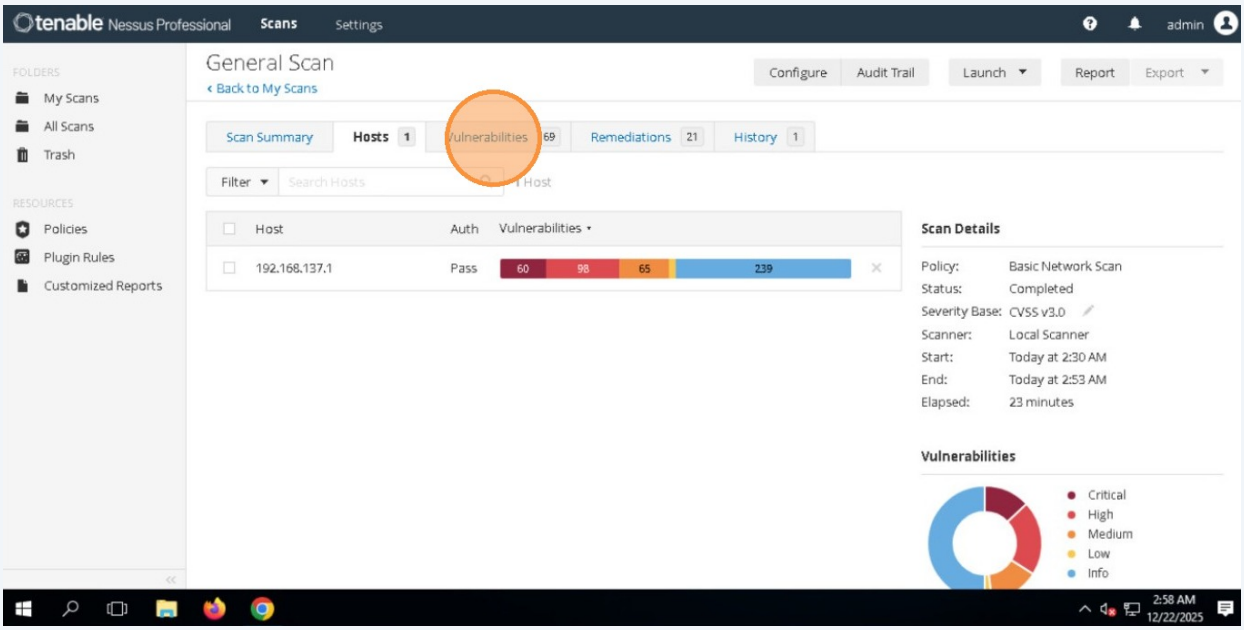
6 I initiated the network scan, allowing Nessus to probe the target for open ports, running services, and known vulnerabilities. The scanner performs automated checks using a large database of vulnerability signatures.



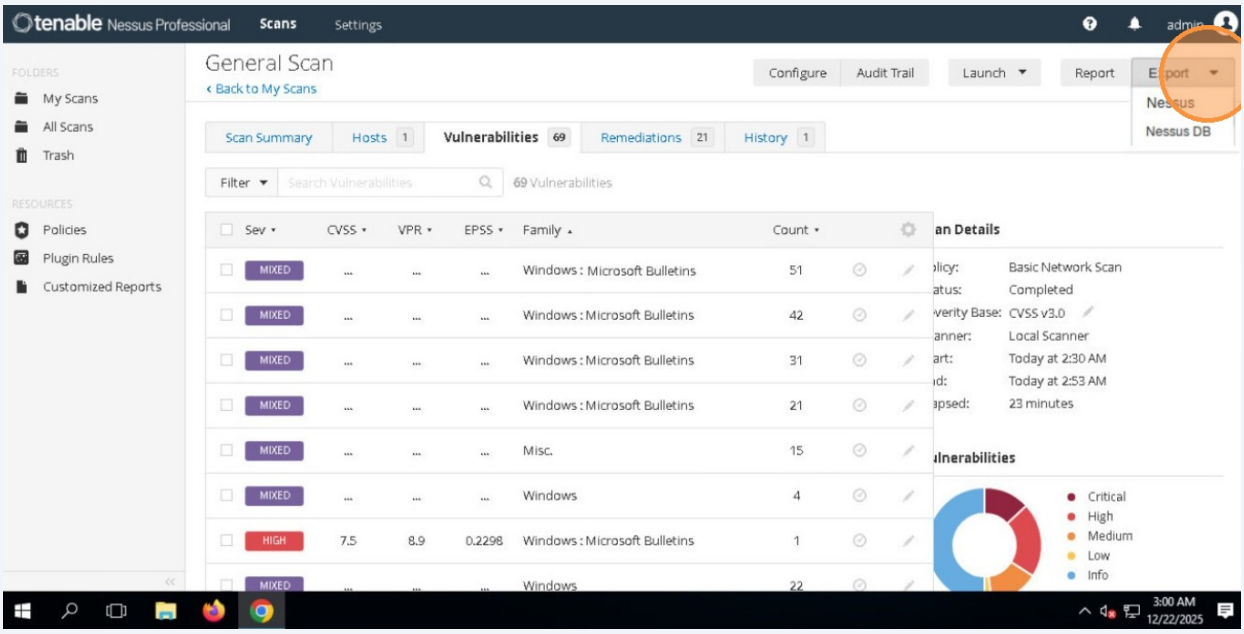
7 During execution, Nessus analyzed the target by enumerating open ports and identifying active services. This process helps build a profile of the system and reveals potential entry points for attackers.



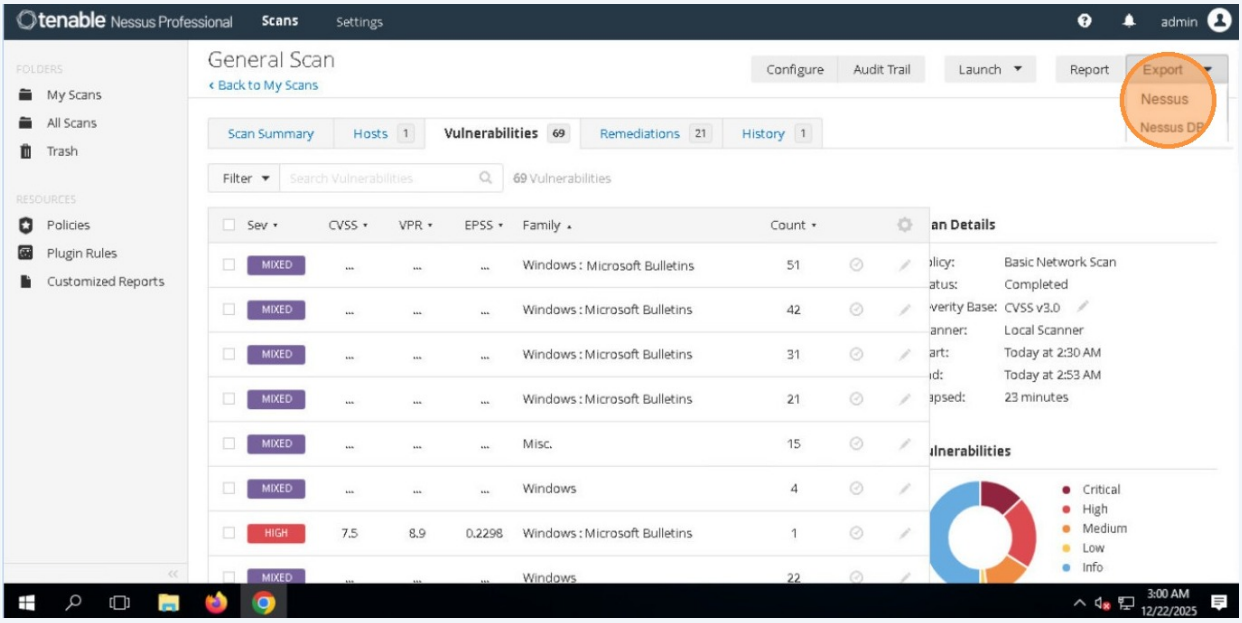
8 I reviewed the scan results, which included identified vulnerabilities, open ports, and service details. Findings are typically categorized by severity (e.g., Low, Medium, High, Critical) to prioritize remediation efforts.



9 I examined specific findings in detail to understand the associated risks, affected services, and potential impact. This step is essential for determining how vulnerabilities could be exploited in a real-world scenario.



10 I documented the key findings from the scan, including exposed ports and identified vulnerabilities, to support further analysis and remediation planning.



Security Impact Analysis

11 This project highlights the importance of network vulnerability scanning in identifying exposed ports, running services, and associated security risks. Using Nessus, I was able to analyze how systems expose services that may be leveraged by attackers if not properly secured. The exercise reinforces the need to prioritize vulnerabilities based on severity and demonstrates how automated scanning supports proactive risk management and strengthens overall network security.
