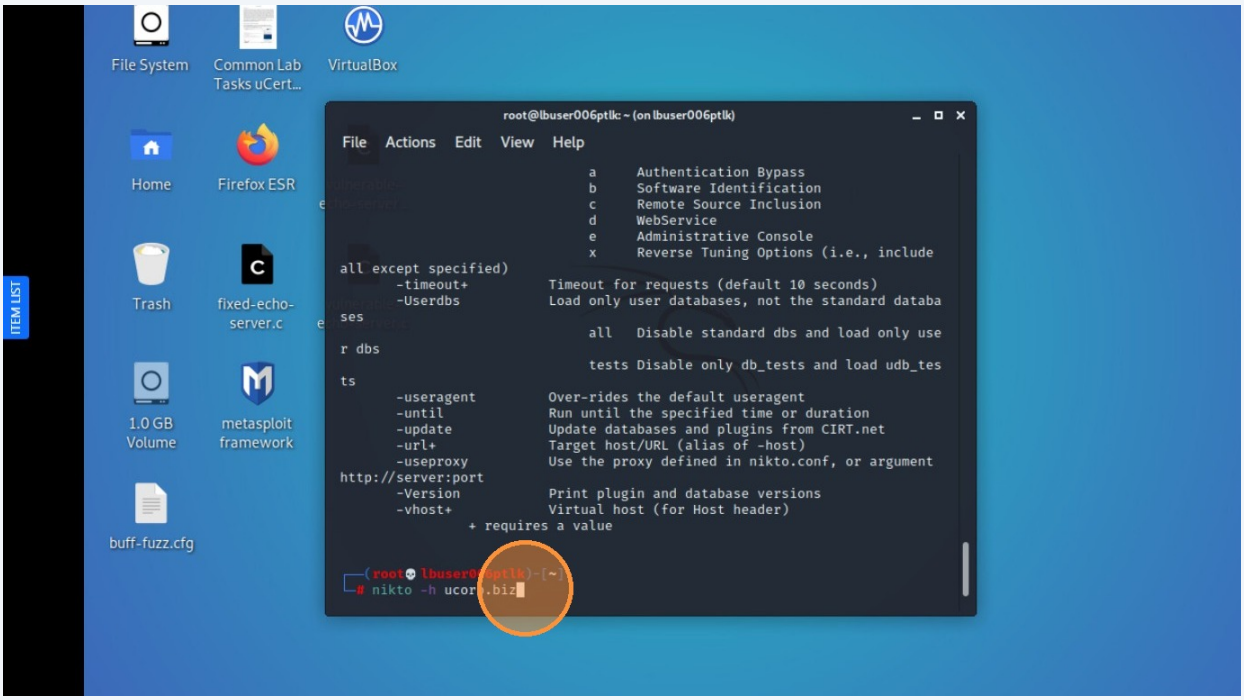
Nikto

Performed web server vulnerability scanning using Nikto to identify potential security weaknesses, including misconfigurations, outdated software, and exposed files. This project demonstrates practical experience in vulnerability assessment and analyzing web server responses from a security perspective.

Cybersecurity-Portfolio: https://github.com/ingridsec/Projects

1 I initiated the vulnerability assessment by accessing a Kali Linux environment and preparing to use Nikto, an open-source web server scanner used to identify misconfigurations, outdated software, and known vulnerabilities.

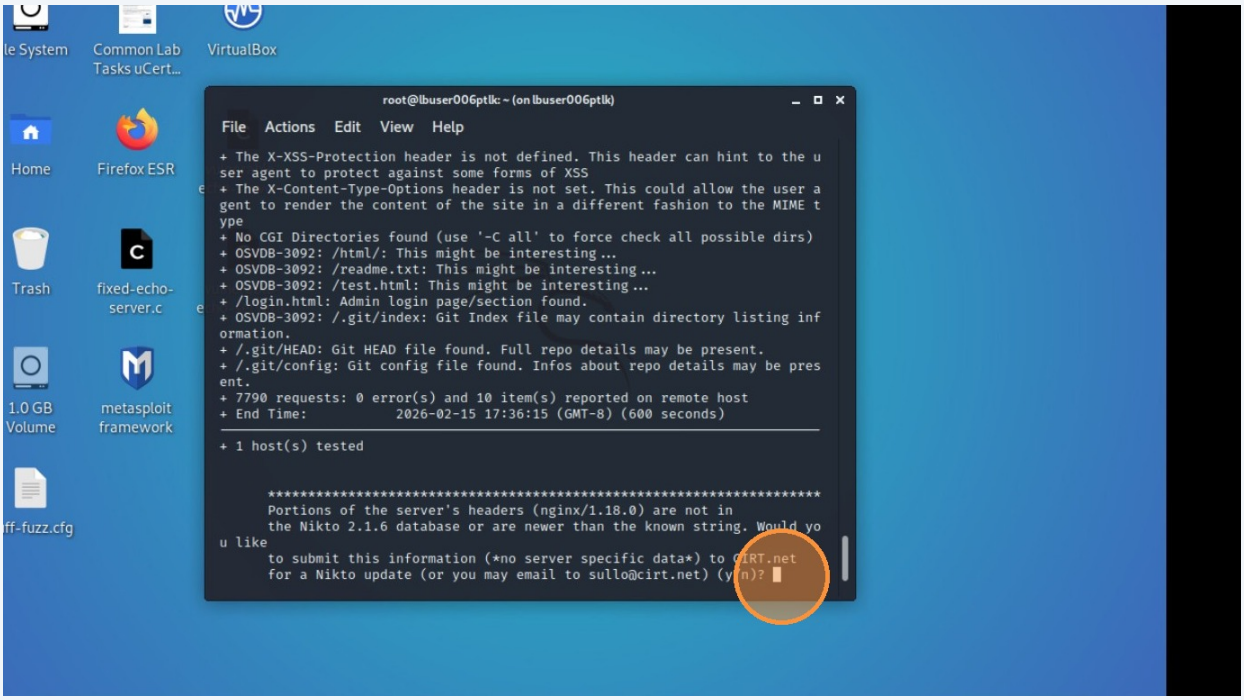
I defined the target web server to ensure the scan remained within scope and aligned with authorized testing boundaries.



2

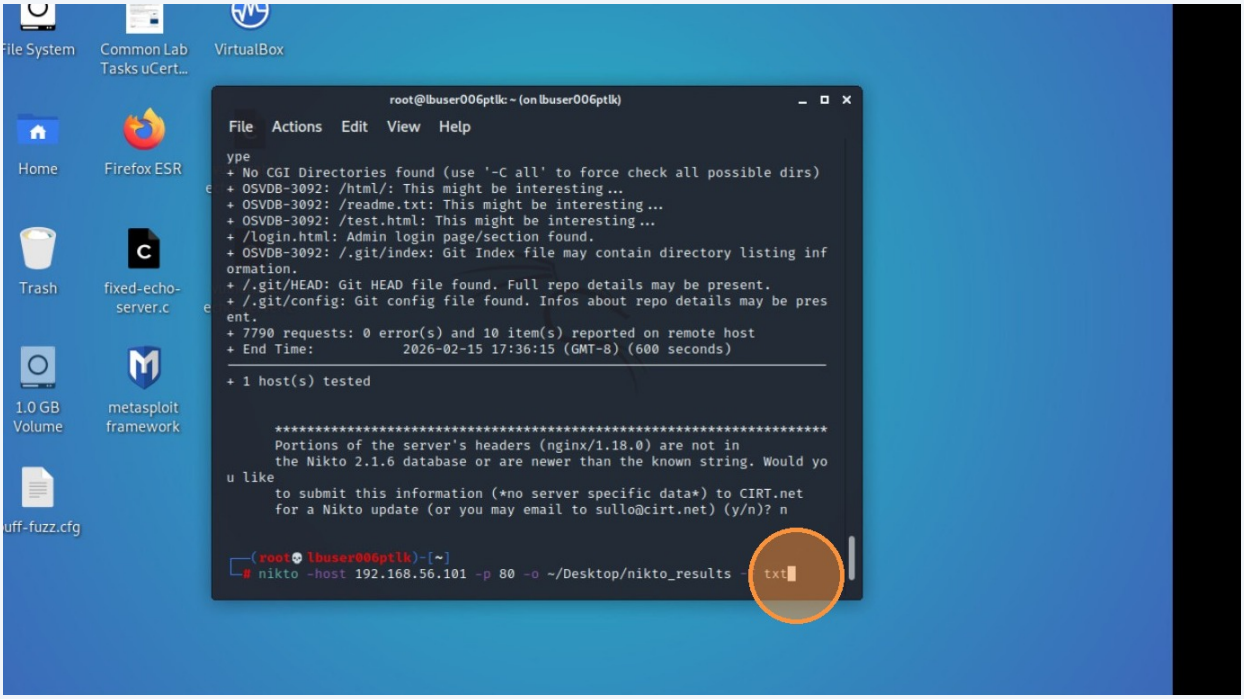
I executed the Nikto scan against the target web server. During this process, Nikto sent multiple HTTP requests to analyze server responses and detect potential vulnerabilities.

The tool performs automated checks against a large database of known issues, including insecure files, outdated server components, and missing security controls.



3 I analyzed the scan results to identify potential security risks such as exposed directories, outdated software versions, and missing security headers.

These findings provide insight into the target's security posture and highlight areas that could be exploited if not properly secured.



4 This project demonstrates how automated vulnerability scanning tools like Nikto can efficiently identify web server misconfigurations, outdated software, and exposed resources that may pose security risks. It emphasizes the importance of analyzing scan results to distinguish meaningful findings from noise and prioritizing vulnerabilities based on potential impact. This workflow mirrors real-world security assessments, where vulnerability scanning plays a key role in reducing attack surface and improving overall system resilience.
